1 Questions

1. (a) $f(x) = -5 + 0.5x^2 + x^5$

   (b) The solution would not work, since we would need a degree 6 polynomial now. This makes sense, since if we added a row to multiply, there would not be enough columns in A to match up with x's rows.

   (c) $det(V) = 0 \iff \exists x_i, x_j (x_i = x_j, i \neq j)$

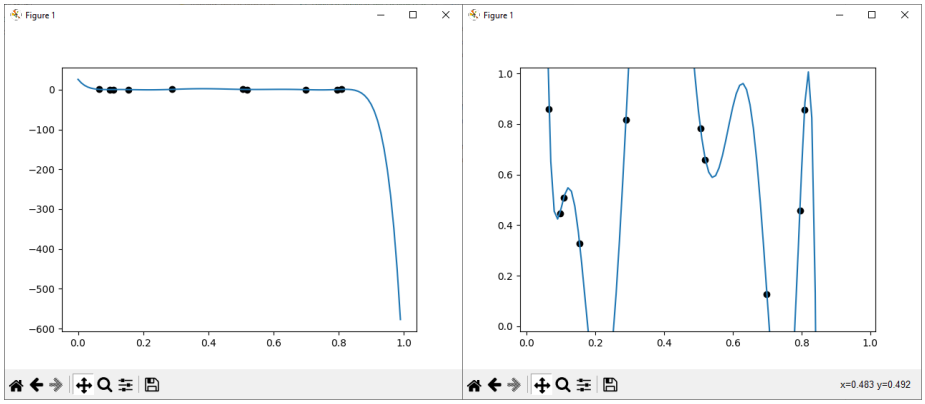

Figure 1: Zoomed out and in views of the data set

   (d) See Figure 1 and section 3.

   (e) We can use spline interpretation to form a piecewise function comprised ofseveral small polynomials to make the graph much better reflect the data points.

2. (a) $\lambda_1 = 5.652811297306327$

   (b) $\lambda_2 = 1.3215412408013711$

2 Code

```
import numpy as np
import numpy.matlib as ml
import numpy.linalg as linalg
import matplotlib.pyplot as plt
import matplotlib.colors as mcolors

def interpolate(x_in: list[float], y_in: list[float]) -> list[float]:
  a: list[list[float]] = []
  for i in range(len(x_in)):
    a.append([])
    for j in range(len(x_in)):
      a[i].append(pow(x_in[i], j))

  a_mat = ml.mat(a)
  a_inverse = linalg.inv(a_mat)

  output = np.matmul(a_inverse, ml.transpose(y_in)).tolist()

  for i in range(len(output)):
    for j in range(len(output[i])):
      output[i][j] = round(output[i][j], 2)

  return output

def power_method(AtA: list[list[float]], x_0: list[float]) -> float:
  x = x_0
  eigenvalue = 0
  for _ in range(20):
    y_i = np.matmul(AtA, x)

    y_transpose_y = np.matmul(ml.transpose(y_i), y_i)
    eigenvalue = np.sqrt(np.sqrt(y_transpose_y))
    x = y_i / eigenvalue

  return eigenvalue

def main():
  # Question 1
  print("1a.", end=" ")
  one_a = interpolate(
    x_in = [0., -1., 1., 2., 4., -2.],
    y_in = [-5., -5.5, -3.5, 29., 1027., -35.]
  )
  print(one_a)
```

```
print("1d.", end=" ")
# x_in = np.random.uniform(low=0, high=1, size=10)
